

**FUNCTIONS OF THE KIDNEY:**

- Foreign & metabolic waste excretion
- Gluconeogenesis
- Regulation of:
  - Water & electrolyte balance
  - Extracellular fluid volume
  - Plasma osmolality
  - Red blood cell production
  - Vascular resistance
  - Acid-base balance
  - Vitamin D production

**WATER AND ELECTROLYTE BALANCE:**

- Nephron reabsorbs most (65%) Na, Cl, bicarbonate
  - > Extent of reabsorption depends on hydration status
- ADH secreted by pituitary gland
  - > Low volume = MORE ADH
  - > High osmotic pressure = LESS ADH
- ADH works at distal nephron (collecting duct) to increase reabsorption of water (↓diuresis)
- Alcohol inhibits release of ADH

**HF – Na & H<sub>2</sub>O EXCRETION OFF-TRACK:**

1. Weakened cardiac muscle (chronic HT, MI, alcohol, infxn, AFIB, valvular disease, etc)
2. Pump volume & efficiency drops off
3. Body compensates: MORE renin, AT2, ADH → MORE sodium/water excretion → MORE BP
4. Stimulates heart
5. Excess fluid volume = edema in lungs/periphery
6. Solves problem temporarily but over time worsens structural changes in heart → further decreasing fxn

**ANATOMY OF THE KIDNEY:**

- **Afferent arteriole:** feeds blood TO glomerulus
- **Efferent arteriole:** drains blood OUT of glomerulus
- **Bowman's capsule:** hollow sphere of epithelial cells, receives filtrate
- **Glomerulus:** where filtration occurs
  - Fenestrated capillaries
  - Podocyte cell bodies
- **Juxtaglomerular apparatus**
  1. Detects flow rate
  2. Detects filtrate composition
  3. Produces renin (hormone that controls renal fxn via modifying bp)
    - STIMULATED BY:
      - a. LOW renal perfusion pressure
      - b. Activation of B1 receptors (epinephrine)

\* ALL will directly/indirectly affect GFR\*

**EXCRETION:**

1. **Glomerular Filtration**
  - Fluid from glomerular capillaries into Bowman's capsule
  - Large plasma proteins (**albumin**) = 99.98% **RETAINED** in circulation
  - Protein-bound substances (Ca<sup>2+</sup>) = **RETAINED**
  - Electrolytes (Na, K, Cl, bicarb), glucose, urea, amino acids, insulin, ADH = **FREELY FILTERED**
2. **Tubular secretion** (LITTLE)
  - K<sup>+</sup> (in exchange with Na<sup>+</sup>)
  - H<sup>+</sup> (in exchange with K<sup>+</sup>)
3. **Tubular reabsorption** (LOTS)
  - **Urea** (50% reabsorbed)
  - H<sub>2</sub>O, electrolytes (99%)
  - **Glucose** (100%)

**FILTRATION BARRIER:** lined with "fixed polyanions" (-ve charge) = repels -ve macromolecules (plasma proteins) [but not minerals like Cl<sup>-</sup> or bicarb]

**GLOMERULAR FILTRATION RATE:**

- GFR = volume of filtrate formed per unit time (mL/min)
- GFR reference values
  1. Normal: ≥ 90 mL/min
  2. Mildly decreased: 60 – 89 mL/min
  3. Moderately decreased: 30-59 mL/min
  4. Severely decreased: 15-29 mL/min
  5. Kidney failure: < 15 mL/min

**CONSIDER:**

- Healthy young adult male GFR = 125 mL/min (= 180 L/day)
- Average total volume of plasma = 3L = kidney filters through body's plasma 60x per day
- As we age, GFR decreases as the number of functional nephrons diminishes

**GFR IS SENSITIVE TO PRESSURES:**

**Forces**

**Favoring filtration:** Glomerular capillary blood pressure ( $P_{GC}$ )

**Opposing filtration:** Fluid pressure in Bowman's space ( $P_{BS}$ ), Osmotic force due to protein in plasma ( $\pi_{GC}$ )

**Net glomerular filtration pressure =  $P_{GC} - P_{BS} - \pi_{GC}$**

**OBSTRUCTION:**

- ↑ opposing forces (fluid pressure) because filtrate can't move through
- ↓ causes net decrease in filtration pressure = decreases GFR

**GLOMERULAR CAPILLARY HYDROSTATIC PRESSURE:**

	DECREASED GFR	INCREASED GFR
<b>CONSTRICTION</b>	<p><b>Constrict AA</b></p> <p>↓ <math>P_{GC}</math></p> <p>↓ GFR</p>	<p><b>Constrict EA</b></p> <p>↑ <math>P_{GC}</math></p> <p>↑ GFR</p> <p>*Angiotensin 2 contributes to this effect.</p>
<b>DILATION</b>	<p><b>Dilate EA</b></p> <p>↓ <math>P_{GC}</math></p> <p>↓ GFR</p>	<p><b>Dilate AA</b></p> <p>↑ <math>P_{GC}</math></p> <p>↑ GFR</p> <p>*renal prostaglandins contribute to this effect.</p>

**HEMATOPOIESIS:**

- Production of erythrocytes, platelets, and leukocytes from undifferentiated stem cells
- Average person produces > 200 billion new blood cells per day
- Requires 3 essential nutrients **PLUS hematopoietic growth factor:**

1. **IRON:** forms iron-porphyrin heme ring and binds oxygen
2. **VITAMIN B12** ([cyano]cobalamin): required for conversion of folate to its cofactors, reducing ability to synthesize DNA for rapidly dividing cells
3. **FOLIC ACID:** essential for DNA synthesis
4. **ERYTHROPOETIN (EPO):** hematopoietic growth factor produced by kidneys; stimulates production & release of reticulocytes when oxygen levels in blood are low (as a result of blood loss, pathological destruction, normal cell death...)

**BONE-MINERAL METABOLISM most dependent upon...**

Calcium	<ul style="list-style-type: none"> <li>• 99% in bone as hydroxyapatite (complex of calcium &amp; phosphate)</li> <li>• Of remaining 1% ...               <ul style="list-style-type: none"> <li>◦ Half is free ionized form</li> <li>◦ Half is protein-bound (to albumin)</li> </ul> </li> <li>• Critical to cell membrane depolarization and neurotransmission</li> <li>• Absorbed via GIT</li> </ul>
Phosphate	<ul style="list-style-type: none"> <li>• 85% in bone as hydroxyapatite; 14% intracellular; 1% ECF</li> <li>• Plentiful in our diet, absorbed from the GIT</li> </ul>
Vitamin D (calcitriol)	<ul style="list-style-type: none"> <li>• Binds and stimulates absorption of calcium from GIT</li> <li>• Inactive forms → hydroxylation at 25<sup>th</sup> position (hepatic) and at 1<sup>st</sup> position (<b>renal</b>) → calcitriol (active form)               <ul style="list-style-type: none"> <li>◦ Vit D2 (ergocaliferol) – inactive form ingested in food</li> <li>◦ Vit D3 (cholecalciferol) – inactive form synthesized in skin</li> </ul> </li> </ul>
PTH (parathyroid hormone)	<ul style="list-style-type: none"> <li>• 4 glands embedded in thyroid gland in neck</li> <li>• Provides hormonal control of calcium and phosphate balance:               <ul style="list-style-type: none"> <li>◦ Keeps plasma level of Ca at a range that doesn't require excitability of cell function</li> <li>◦ Maintains bone integrity</li> </ul> </li> </ul>
Calcitonin	<ul style="list-style-type: none"> <li>• Released by thyroid gland</li> <li>• Inhibits action of osteoCLASTS (which inhibits calcium breakdown from bone)</li> <li>• Decreased plasma calcium levels</li> </ul>
Fibroblast Growth Factor 23 (FGF 23)
